

(Social Choice and) Mechanism Design on Social Networks

Dengji Zhao

ShanghaiTech University, Shanghai, China

A tutorial @ AAMAS 2019

2009 DARPA Red Balloon Challenge

- The \$40,000 challenge award would be granted to the first team to submit the locations of 10 moored, 8-foot, red weather balloons at 10 previously undisclosed fixed locations in the continental United States.

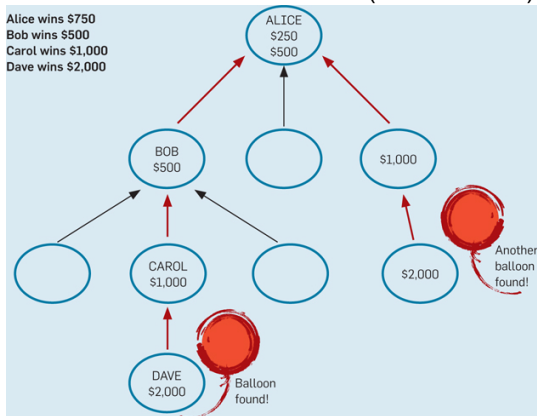

2009 DARPA Red Balloon Challenge

MIT Crowdsourced Solution (The Winner):

- *"We're giving \$2000 per balloon to the first person to send us the correct coordinates, but that's not all – we're also giving \$1000 to the person who invited them. Then we're giving \$500 whoever invited the inviter, and \$250 to whoever invited them, and so on ..."*
- got over 5,000 of participants, won the competition in under 9 hours.

2009 DARPA Red Balloon Challenge

MIT Crowdsourced Solution (The Winner):

- Pickard, G., et al., **Time-Critical Social Mobilization**. Science, 2011. 334(6055): p. 509-12.

PinDuoDuo (like Groupon)

人人都是产品经理
WWW.WOSHIPM.COM

The logo is a red heart shape composed of 12 hexagons. The central hexagon contains the Chinese character '拼' (Pīn), which means 'to join' or 'to share'. The surrounding 11 hexagons contain various white icons representing different product categories: a dress, a t-shirt, a wine glass, an apple, a handbag, a fish, a high-heeled shoe, a camera, a smartwatch, a coffee cup, an umbrella, and a shopping bag.

3亿人都在“拼多多”

拼团价 ¥49.9

单买价 ¥99.9

The smartphone screen displays the Pinduoduo app interface. At the top, it says '拼多多' (Pinduoduo). Below that, there's a banner for a product (nuts) with the group price '拼团价 ¥49.9' and the individual price '单买价 ¥99.9'. At the bottom of the screen, there's a red button with the text '拼一下' (Join now) and a price '¥49.90'.

A woman in a red sweater is smiling and holding a large, wrapped gift box. She is standing next to the smartphone, which is displaying the Pinduoduo app interface.

PinDuoDuo (like Groupon)

Achievements:

- went online in Sep 2015
- got over 2 million users in two weeks
- by Feb 2016, got over 20 million users
- IPO in Jul 2018

PinDuoDuo (like Groupon)

Their group buying model:

- 1 choose one product
- 2 join a group buying deal or initiate a new group buying deal
- 3 wait or invite friends to join the deal
- 4 when the required number of buyers is reached, they all buy the product with a cheaper price

What are the incentives?

More participants, higher chance to win!!!

- 2009 DARPA Red Balloon Challenge
 - Inviting more friends has **higher chance to win** (higher utility)
- PinDuoDuo
 - Inviting more friends has **higher chance to get cheap items** (higher utility)

What if it is a competition?

- resource allocation such as auctions
- task allocation

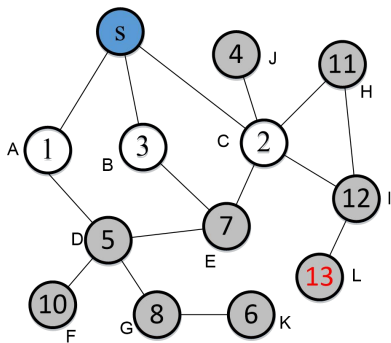

More participants means lower chance to win!!!

Diffusion Mechanism Design

Mechanism Design on Social Networks

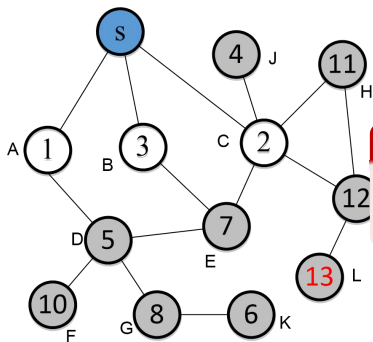

Design mechanisms/markets under competitive environment such that participants are incentivized to invite more participants/competitors to join the mechanisms.

Starter: Promote a Sale in Social Networks

- The seller (blue node) sells one item and has only three connections/neighbours in the network (A,B,C).
- Each node is a potential buyer and the value is her highest willing payment to buy the item (valuation).
- The seller's revenue of applying second price auction without promotion is 2.
- but the highest willing payment of the network is 13.

Starter: Promote a Sale in Social Networks

Question

How the seller could do to increase her profit?

Traditional Sale Promotions

Traditional sale promotions:

- Promotions in **shopping centres**
- Keywords based ads via **search engines** such as Google
- Ads via **social media** such as WeChat, Facebook, Twitter

Traditional Sale Promotions

Traditional sale promotions:

- Promotions in **shopping centres**
- Keywords based ads via **search engines** such as Google
- Ads via **social media** such as WeChat, Facebook, Twitter

Challenge

- The return of these promotions are unpredictable.
- The seller may **LOSE** from the promotions.

Tackle the Challenge

Build promotion inside the market mechanism such that

- 1 the promotion will **never bring negative utility/revenue** to the seller.
- 2 all **buyers** who are aware of the sale **are incentivized to diffuse the sale information** to all her neighbours.

Tackle the Challenge

Build promotion inside the market mechanism such that

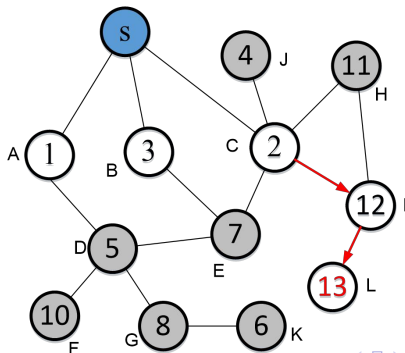

- 1 the promotion will **never bring negative utility/revenue** to the seller.
- 2 all **buyers** who are aware of the sale **are incentivized to diffuse the sale information** to all her neighbours.

"Diffusion Mechanism Design"

New Challenges

Why a buyer would bring more buyers to compete with her?

- only if their **efforts** are **rewarded**, *but the seller doesn't want to lose!*
- we **cannot** just **pay** each node a **fixed amount** to incentivise them to diffuse the information.

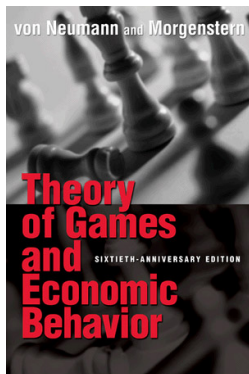

What is Mechanism Design

What is Mechanism/Market Design?

- it is known as Reverse Game Theory

What is Game Theory

- **Game theory** is the study of mathematical models of **conflict** and **cooperation** between intelligent rational decision-makers (wiki) [von Neumann and Morgenstern 1944].

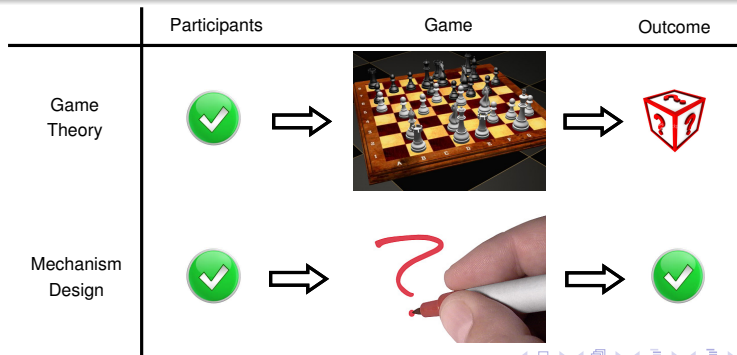

- **Non-cooperative games**: Go, poker, rock-paper-scissors
- **Cooperative games**: coordination games

Mechanism Design (Reverse Game Theory)

Mechanism Design is to answer...

Question

How to **design** a mechanism/game, toward desired objectives, in strategic settings?

Mechanism Design (Reverse Game Theory)

Mechanism Design is to answer...

Question

How to **design** a mechanism/game, toward desired objectives, in strategic settings?

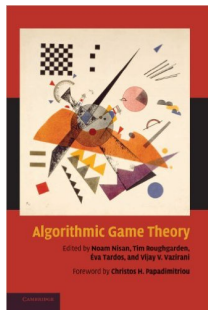

Roger B. Myerson (born March 29, 1951, University of Chicago, US)

- **Nobel Prize** for economics (2007), for "having laid the foundations of **mechanism design theory**."
- ***Eleven game-theorists** have won the economics Nobel Prize.*

Algorithmic Game Theory (AGT)

- **Algorithmic game theory** is an area in the intersection of **game theory** and **algorithm design**, whose objective is to design algorithms in strategic environments (wiki) [Nisan et al. 2007].

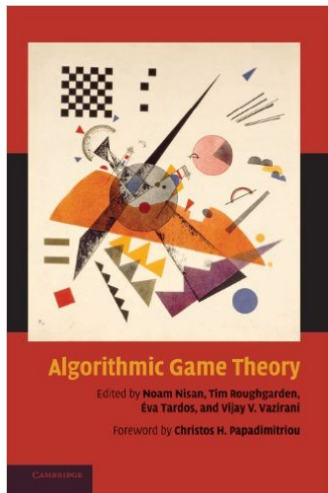

- *Computing in Games*: algorithms for computing equilibria
- *Algorithmic Mechanism Design*: design games that have both good game-theoretical and algorithmic properties
- ...

Algorithmic Game Theory in Artificial Intelligence

- Algorithmic game theory research in AI:
 - **Game Playing**: computation challenges, AlphaGo, poker
 - **Social Choice**: preferences aggregation, voting, prediction
 - **Mechanism Design**: the allocation of scarce resources, ad auctions
- Many IJCAI Computers and Thought Award (outstanding young scientists in artificial intelligence) winners had worked on AGT:
 - Sarit Kraus (1995), Nicholas Jennings (1999), Tuomas Sandholm (2003), Peter Stone (2007), Vincent Conitzer (2011), and Ariel Procaccia (2015)

A Mechanism Design Example

A Simple Mechanism Design Example

Design Goal

How can a house-seller sell her house with the "highest" profit?

A Mechanism Design Example

Design Goal

How can a house-seller sell her house with the "highest" profit?

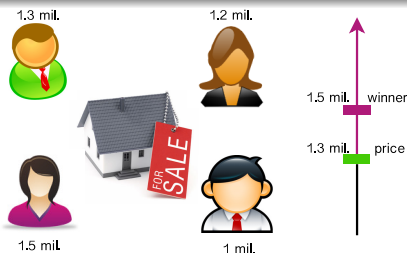

- **Challenge:** the seller **doesn't know** how much the buyers are willing to pay (**their valuations**).

A Mechanism Design Example

Design Goal

How can a house-seller sell her house with the "highest" profit?

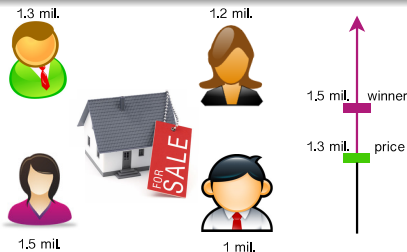

Solution: Second Price Auction (Vickrey Auction/VCG)

- **Input:** each buyer reports a price/bid to the seller
- **Output:** the seller decides
 - *allocation:* the agent with the highest price wins.
 - *payment:* the winner pays the second highest price.

A Mechanism Design Example

Design Goal

How can a house-seller sell her house with the "highest" profit?

Solution: **Second Price Auction** (Vickrey Auction/VCG)

Properties:

- **Efficient:** maximising **social welfare**
- **Truthful:** buyers **report** their valuations **truthfully**

Is this the BEST the seller can do?

Question

What can the seller do to FURTHER increase her profit?

Is this the BEST the seller can do?

Question

What can the seller do to FURTHER increase her profit?

- estimate a good **reserve price** [Myerson 1981]
 - *requires a good estimation of buyers' valuations*
- **promotions**: let more people know/participate in the auction

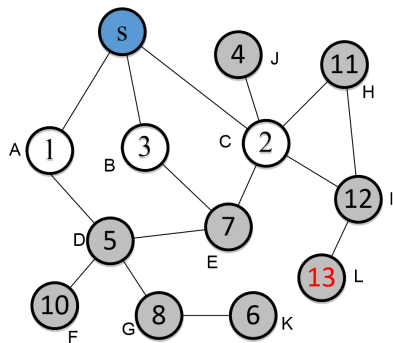

Is this the BEST the seller can do?

Question

What can the seller do to FURTHER increase her profit?

- estimate a good **reserve price** [Myerson 1981]
 - *requires a good estimation of buyers' valuations*
- **promotions**: let more people know/participate in the auction

Recap: Promote a Sale in Social Networks

- The seller (**blue node**) sells one item and has only three connections in the network (A,B,C).
- Each node is a potential buyer and the value is her highest willing payment to buy the item (**valuation**).
- Profit of applying second price auction without promotion is **2**.
- but the highest willing payment of the network is **13**.

Traditional Sale Promotions

Traditional sale promotions:

- Promotions in **shopping centres**
- Keywords based ads via **search engines** such as Google
- Ads via **social media** such as WeChat, Facebook, Twitter

Challenge

- The return of these promotions are unpredictable.
- The seller may **LOSE** from the promotions.

Tackle the Challenge

Build promotion inside the market mechanism such that

- 1 the promotion will **never bring negative utility/revenue** to the seller.
- 2 all **buyers** who are aware of the sale **are incentivized to diffuse the sale information** to all her neighbours.

"Diffusion Mechanism Design"

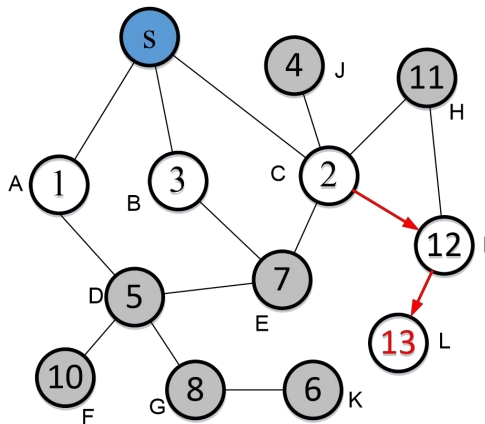

Information Diffusion Mechanisms

- Bin Li, Dong Hao, Dengji Zhao, Tao Zhou: **Mechanism Design in Social Networks**. AAAI'17.
- Dengji Zhao, Bin Li, Junping Xu, Dong Hao, Nick Jennings: **Selling Multiple Items via Social Networks**. AAMAS'18.

Information Diffusion Paths

An information diffusion path from the seller to node L:

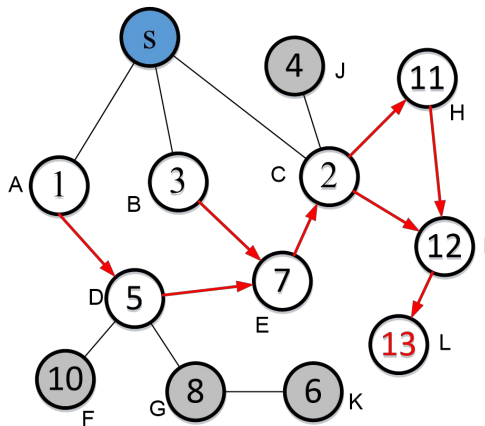

$s \rightarrow C \rightarrow I \rightarrow L$

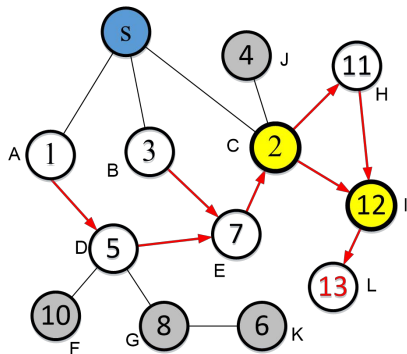

Information Diffusion Paths

An information diffusion path from the seller to node L:

$s \rightarrow C \rightarrow I \rightarrow L$

Diffusion Critical Nodes

Definition

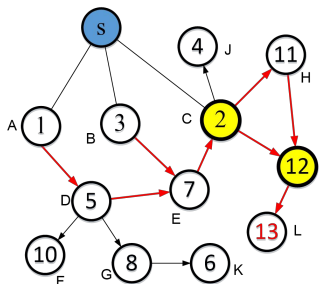

i is j 's **diffusion critical node** if **all** the information diffusion **paths** started from the seller s to j have to **pass** i .

- nodes **C** and **I** are L's only diffusion critical nodes.

Information Diffusion Mechanism [Li et al. AAI'17]

The **payment** definition (second-price-like):

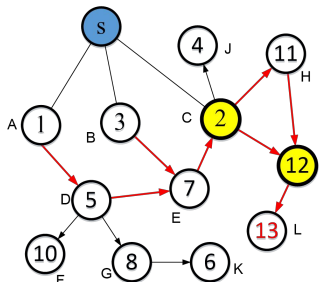

- If a buyer or one of her "*diffusion critical children*" gets the item, then the buyer pays **the highest bid of the others** (without the buyer's participation);
- otherwise, her payment is zero.

Information Diffusion Mechanism [Li et al. AAI'17]

The **payment** definition (second-price-like):

- If a buyer or one of her "*diffusion critical children*" gets the item, then the buyer pays **the highest bid of the others** (without the buyer's participation);
- otherwise, her payment is zero.

If the item is allocated to *L*, the payments of *C*, *I* and *L* are **10, 11, 12** respectively .

Information Diffusion Mechanism

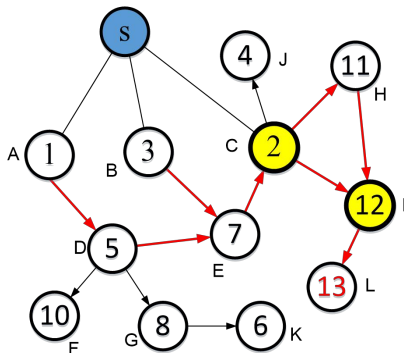

The **allocation** definition:

- Identify the node i with the highest bid and the node's **diffusion critical node path** $P_{c_i} = (c_i^1, c_i^2, \dots, i)$.
- Give the item to the first node of P_{c_i} , the node pays to the seller and then decides to whether keep the item or pass it to the next node in P_{c_i} :
 - If **the payment of the next node is greater than the bid of the current node**, passes it to the next node and receives the payment from the next node; the next node makes a similar decision;
 - otherwise, keep the item.

The Information Diffusion Mechanism

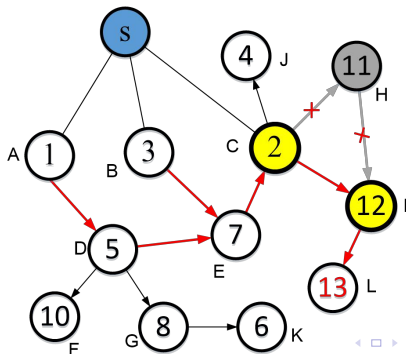

The **outcome** of the Information Diffusion Mechanism:

- the item is allocated to node I.
- node I pays 11 to C, C pays 10 to the seller.
- the **utilities** of I, C, the seller are 1, 1, 10.

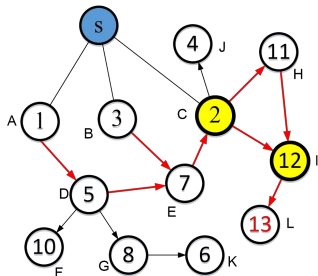

Why Buyers are Happy to Diffuse the Information?

- buyers receive the information earlier have higher priority to win the item (C chooses before I and I chooses before L).
- diffuse the information to more buyers will potentially increase their reward (if C does not invite H , her utility is 0).

Properties of the Information Diffusion Mechanism

- **Truthful**: report true valuation and diffuse the sale information to all her neighbours is a dominate strategy.
- **Individually Rational**: no buyer will receive a negative utility to join the mechanism.
- **Seller's Revenue Improved**: the seller's revenue is non-negative and is \geq that of the VCG without diffusion.

What Next?

- Diffusion mechanisms for combinatorial exchanges
- Diffusion with costs and delays
- Network structure based revenue analysis
- Applications/implementations in the existing social networks
- Other mechanisms to further improve the revenue and/or the efficiency

Diffusion Mechanisms for Combinatorial Exchanges

Challenge

How to generalise the mechanism to combinatorial settings?

Diffusion Mechanisms for Combinatorial Exchanges

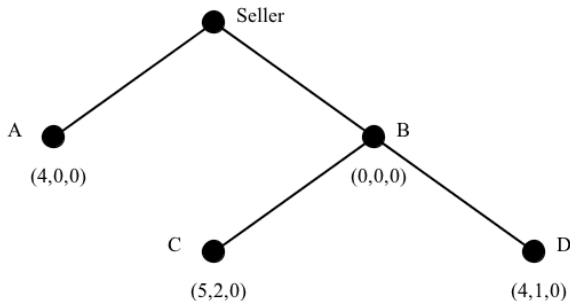

Consider the following simple setting:

- A seller sells three units of one commodity, e.g. MacBook computers.
- Each buyer has a **diminishing marginal utility** for consuming the goods.

Diffusion Mechanisms for Combinatorial Exchanges

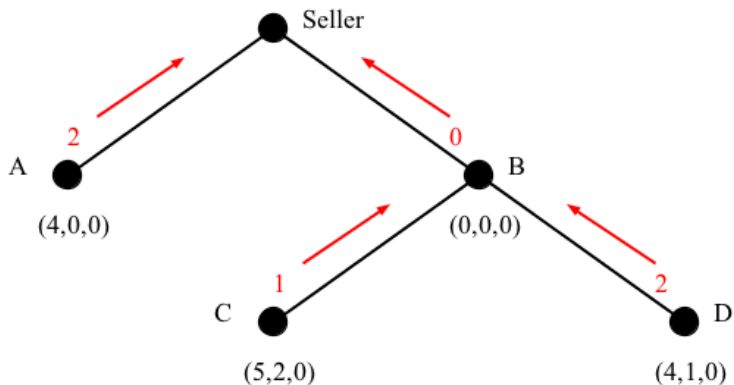

Consider the following simple setting:

- A seller sells three units of one commodity, e.g. MacBook computers.
- Each buyer has a **diminishing marginal utility** for consuming the goods.

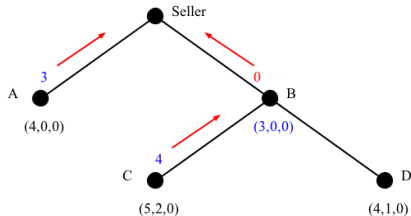

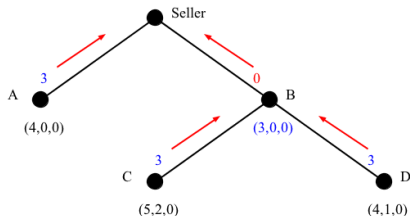

Diffusion Mechanisms for Combinatorial Exchanges

If we simply apply our information diffusion mechanism:

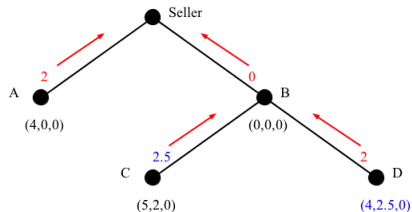

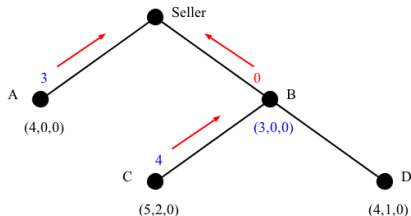

Diffusion Mechanisms for Combinatorial Exchanges

What if buyer B's valuation is $(3, 0, 0)$?

Diffusion Mechanisms for Combinatorial Exchanges

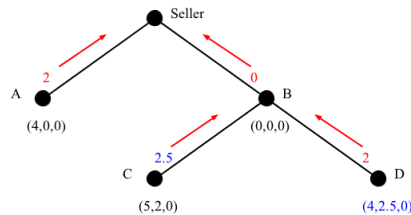

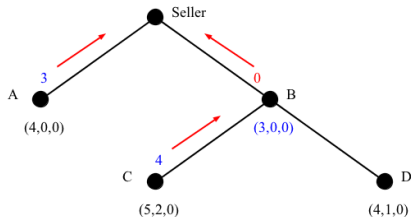

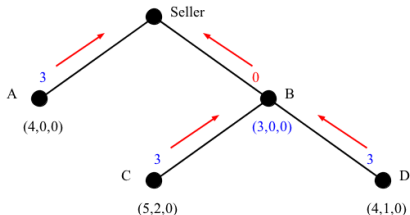

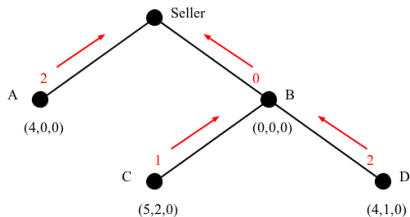

What if buyer D's valuation is $(4, 2.5, 0)$?

Diffusion Mechanisms for Combinatorial Exchanges

Challenge

There is a very complex **Decision Making** at each node!!!

Why is it so complex when there are multiple items?

To achieve truthfulness:

- The mechanism has to **maximise each node's utility** under truthful reporting.
- Each node's **payment** should **not depend on** her **valuation**.

The complexity we had:

- A node can **influence her received payments** by controlling the items passed to her children.
- A node can **influence the payments of her peers**, without changing her own allocation and payments.
- **This leads to a decision loop (very complex optimization) and may not be able to maximise everyone's utility.**

Reduce the Complexity

The Main Idea

A node **CANNOT** influence the payments she receives by controlling the items passed to her children.

Simplify the decision complexity we had:

- A node can ~~influence her received payments~~ by controlling the items passed to her children.
- A node can **influence the payments of her peers**, without changing her own allocation and payments.
- This leads to a decision loop and may not be able to maximise everyone's utility.

Solution Example: Sells Multiple Homogeneous Items

Selling Multiple Items via Social Networks [Zhao et al. AAMAS'18]

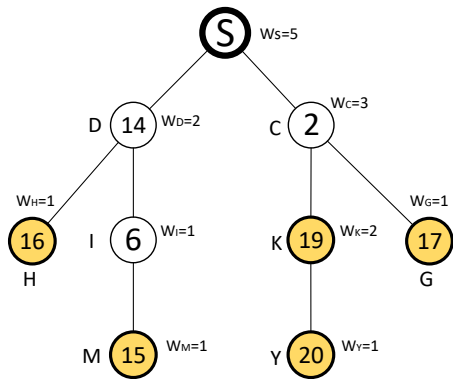

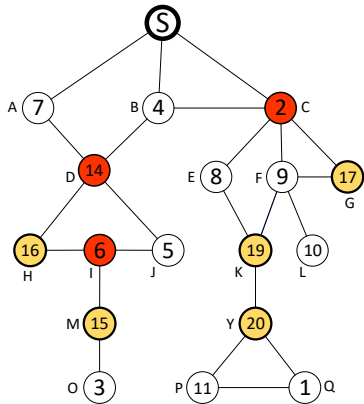

- generalises the result from [Li et al. 2017];
- agent i 's reward/payment doesn't depends on how many of i 's children received items;
- agent pays to the seller directly rather than to their parent;

The Generalised Setting

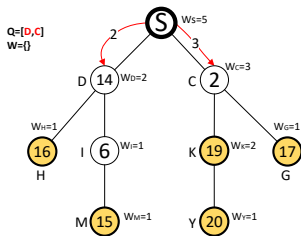

- A seller sells $\mathcal{K} \geq 1$ homogeneous items;
- each buyer requires at most one item (single-unit demand);
- the rest is the same as [Li et al. 2017].

The Generalised Diffusion Mechanism

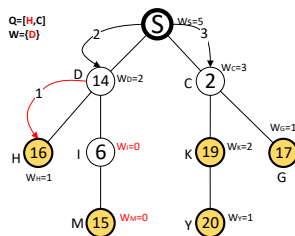

Consider $\mathcal{K} = 5$:

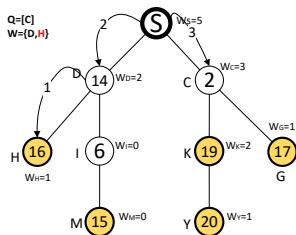

The Generalised Diffusion Mechanism

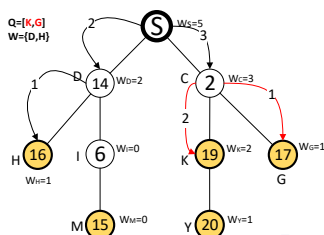

(a)

(b)

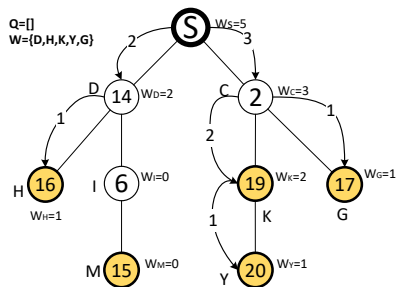

(c)

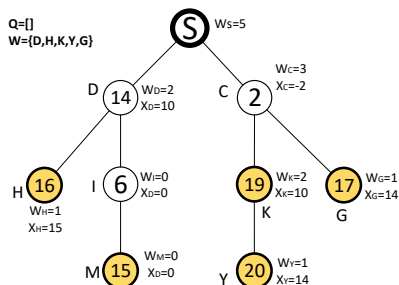

(d)

The Generalised Diffusion Mechanism

(i)

(ii)

The Allocation Policy of the Generalisation

Node/buyer i receives one item if and only if

- 1 the top \mathcal{K} -highest valued children of i (and their parents, who are also i 's children) do not participate
- 2 and i wins under the efficient allocation with their absence

given that all i 's (critical) parents' allocation is determined and fixed.

The Payment Policy of the Generalisation

Node i 's utility is the social welfare difference of the efficient allocation **between**

- 1 the top \mathcal{K} -highest valued children of i (and their parents, who are also i 's children) do not participate (**guarantees that i 's payment does not depend on how many items i 's children get**)
- 2 **and** i (and all her children) does not participate

Formally, i 's payment is:

$$\begin{cases} SW_{-D_i} - (SW_{-C_i^{\mathcal{K}}} - v'_i) & \text{if } i \in W, \\ SW_{-D_i} - SW_{-C_i^{\mathcal{K}}} & \text{if } i \in \bigcup_{j \in W} \mathcal{P}_j(\theta') \setminus W, \\ 0 & \text{otherwise.} \end{cases}$$

where W is the set of nodes each of whom received one item.

Properties of the Generalisation

- **Truthful**: report true valuation and **diffuse the sale information to all her neighbours** is a dominate strategy for each node.
- **Individually Rational**: no node will receive a negative utility to join the mechanism.
- **Seller's Revenue Improved**: the seller's revenue is **non-negative** and is \geq **that of the VCG without diffusion**.

Truthfulness and IR

Given i 's payment:

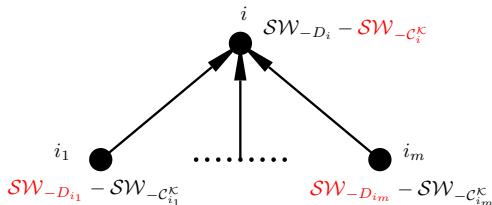

$$\begin{cases} SW_{-D_i} - (SW_{-C_i^K} - v'_i) & \text{if } i \in W, \\ SW_{-D_i} - SW_{-C_i^K} & \text{if } i \in \bigcup_{j \in W} \mathcal{P}_j(\theta') \setminus W, \\ 0 & \text{otherwise.} \end{cases}$$

if i reports truthfully, i 's utility is:

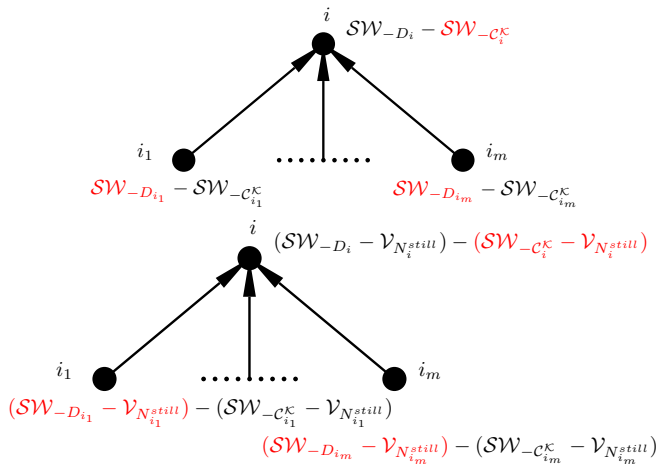

$$SW_{-C_i^K} - SW_{-D_i}$$

- SW_{-D_i} is the optimal social welfare without i 's participation
- $SW_{-C_i^K}$ is the optimal social welfare when the top K -highest valued children of i (and their parents, who are also i 's children) do not participate

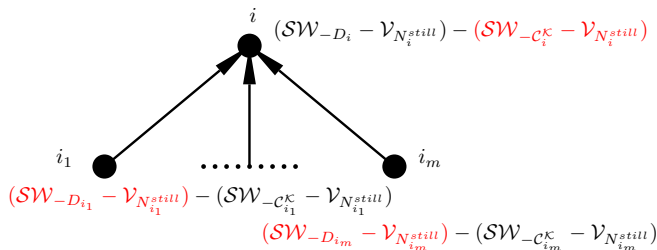

Guaranteed Revenue Improvement for the Seller

Guaranteed Revenue Improvement for the Seller

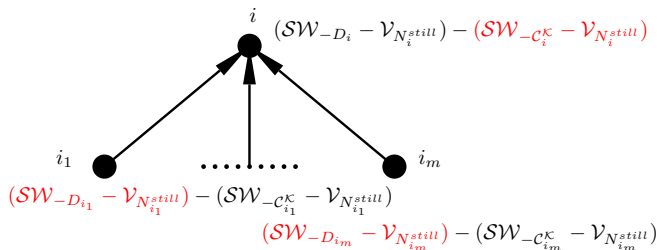

Guaranteed Revenue Improvement for the Seller

$$SW_{-C_i^K} - \mathcal{V}_{N_i^{still}} \leq \sum_{i_l} (SW_{-D_{i_l}} - \mathcal{V}_{N_{i_l}^{still}})$$

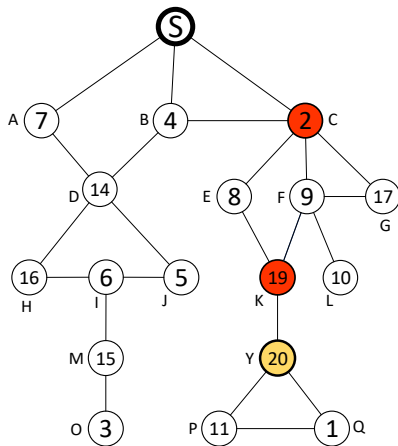

Guaranteed Revenue Improvement for the Seller

Theorem (Zhao et al. 2018)

The revenue of the generalised information diffusion mechanism is greater than or equal to $\mathcal{K} \times v_{\mathcal{K}+1}$, where $v_{\mathcal{K}+1}$ is the $(\mathcal{K} + 1)$ -th largest valuation report among r_s , assume that $|r_s| > \mathcal{K}$.

What happens when $\mathcal{K} = 1$?

Open Questions

- More general settings
 - characterize truthful diffusion mechanisms, **revenue monotonicity** is the key?
- When there is a diffusion cost
 - how to guarantee the seller will not lose?
- Privacy concern and the seller's strategies
 - the seller discovery the whole network and she may cheat as well!
- False-name manipulations
 - a node may create multiple ids as her neighbours to gain more payment?
- many more...

Diffusion Mechanism Design for Task Allocation

- 1 task requires more participants' contribution (**collaboration**)
- 2 but participants' contribution may conflict with each other (**competition**)

An Example: Crowdsourcing Data Acquisition

- a requester is collecting data from the crowd
- more participants gives richer dataset
- participants' contribution depends on the quality of their provided data
- if two participants offer the same data, how to calculate their contribution?

An Example: Crowdsourcing Data Acquisition

- a requester is collecting data from the crowd
- more participants gives richer dataset
- participants' contribution depends on the quality of their provided data
- if two participants offer the same data, how to calculate their contribution?

Shapley Value?

Shapley Value

The problem of the Shapley value:

- two participants offer the same data will share the same Shapley value
 - the Shapley value is doubled if one of them didn't participate

Solution: Layered Shapley Value

Layered Shapley Value:

- participants are layered
- the Shapley value is calculated for each lower layer first
- the calculation for higher layer assumes that lower layers' participants are always in the coalition

Properties:

- participants are incentivized to invite more participants
(new participants do not compete with them)
- the requester does not need to pay for redundant data

Summary

- Diffusion Mechanism for Resource Allocation (competitive environment)
 - for selling single item
 - for selling multiple items
- Diffusion Mechanism for Task Allocation (both competitive and collaborative)
 - crowdsourcing data acquisition
